## Introduction: What are Site Atmospheric State Best Estimates?

Combining measurements to best estimate the temperature above Lauder

Calculating the components of the SASBE

Summary

## Site Atmospheric State Best Estimates (SASBEs)

- ▶ combine measurements from multiple instruments to create the best-possible vertically resolved time series of target parameter above one site
- ▶ contain all available knowledge about the state of target variable at that site
- ▶ include an estimate of the uncertainty on every value
- ▶ useful for satellite/model validation and sensitivity studies

Introduction

Methodology

Components  
of SASBE

Summary

References

- ▶ A temperature SASBE for the distributed GCOS<sup>1</sup> Reference Upper-Air Network (GRUAN) site at Lauder is under development
- ▶ SASBE combines measurements from Lauder and Invercargill
- ▶ Available for 1996-2012
- ▶ Hourly temporal resolution
- ▶ Vertically resolved on standard pressure levels<sup>2</sup>

Introduction

Methodology

Components  
of SASBE

Summary

References

The SASBE is calculated based on:

- ▶ radiosonde temperature profiles from Lauder and Invercargill
- ▶ surface measurements from automatic weather stations in Lauder and Invercargill
- ▶ ERA5 diurnal temperature cycles at Lauder and Invercargill

The temperature anomaly is calculated for both sites.

A regression model is used to best-estimate the temperature anomaly above Lauder from the temperature above Invercargill

The temperature SASBE is then calculated as

$$T_{Lau}(t) = T_{Diur}(t) + \alpha \cdot \sum_{i=1}^n \gamma_i \cdot T'_{Lau_i} + (1 - \alpha) \cdot \sum_{i=1}^m \beta_i \cdot \hat{T}'_{Lau_i} \quad (1)$$

Using:

- ▶ The diurnal cycle
- ▶ weights  $\alpha = \exp\left(-\frac{(t_{Lau_1} - t)^2}{\tau_{Lau}^2}\right)$
- ▶ the weighted temperature anomaly from those Lauder radiosondes that are sufficiently close in time
- ▶ the weighted best-estimate of the temperature anomaly above Lauder obtained from radiosondes launched at Invercargill

Methodology

Components  
of SASBE

Summary

References

- ▶ Diurnal cycle calculated from hourly ERA5 reanalysis for Lauder/Invercargill
- ▶ Fourier series accounting for day of year and hour of day is fit to temperature time series
- ▶ ERA5 includes uncertainties → uncertainties on the diurnal temperatures (see Bodeker and Kremser, 2015)

Figure 1: Diurnal cycle 925 hPa above Lauder at the 1st of January.

- ▶ Temperature anomalies above Lauder correlated with temperature anomalies above Invercargill
- ▶ This interdependence is used to estimate temperature anomaly above Lauder  $\hat{T}'_{Lau}$  from temperature anomaly above Invercargill  $T'_{Inv}$
- ▶ The following regression model is used:

$$\hat{T}'_{Lau} = \alpha + \beta \cdot T'_{Inv} + \eta \cdot \Delta SP + \kappa \cdot \Delta ST' + \epsilon \quad \text{Eq.(4)}$$

- ▶  $\beta$  is expanded in a Fourier series to take the wind direction into account
- ▶ uncertainties propagated through the regression model

- ▶ The final version of the SASBE for Lauder is under development
- ▶ It provides temperature profiles from 1996-2012 with hourly resolution at standard pressure levels
- ▶ The methodology will be published in *Earth System Science Data* (Manuscript in preparation)
- ▶ The data product will be added to the PANGAEA archive (including doi)
- ▶ Outlook: The SASBE can be used to calculate top-of-the-atmosphere radiances with traceable uncertainty estimates (see Tradowsky et al., 2016)  
→ satellite validation and sensitivity study
